Question 1 [C02] [10 Points]

An **online platform** allows users to sign up using an email address. Since the email will be used for account verification and communication, the system must check whether the entered email address is valid before completing the registration.

As a Java developer, your task is to create a program that checks the validity of an email address. The program will take an email address as input and verify it based on simple rules. The email must contain exactly **one @ symbol**, **must not contain any spaces**, and **must have a valid domain name**. The part of the email after @ should contain at least one dot (.), such as in **example.com**.

If the email follows all these rules, the program should print "Valid Email". Otherwise, it should print "Invalid Email".

Sample Input	Sample Output
Enter email: student@bracu.ac.bd	Valid Email
Enter email: rased@gmail.com	Valid Email
Enter email: support@tripadvisor	Invalid Email
