Question 1 [C03] [10 Points]

In a futuristic physics training game, a laser cannon fires energy pulses across a straight battlefield that is divided into **N** energy nodes placed in a line. Each node stores an integer energy value (positive or negative). When the cannon is fired from a node at position **i**, the laser collides with every node after it (positions **i+1** to **N-1**). The collision energy between node **i** and node **j** is calculated as:

$$\text{collisionEnergy} = \text{energy}[i] \times \text{energy}[j]$$

The total collision energy of a firing position **i** is the sum of collision energies between node **i** and all nodes to its right. Your task is to determine the maximum total collision energy that can be produced by choosing the best firing position.

Sample Input	Sample Output
Energy Nodes: 5 2 -1 3 -2 4	Maximum Total Collision Energy: 8
Energy Nodes: 4 35 15 25 -5	Maximum Total Collision Energy: 1225
