Question 1 [C01] [10 Points]

At **BRAC University**, the brilliant **Professor Parity** has introduced an exciting number challenge for his students. Each student must submit a **positive number**. For that number, perform the following:

- Calculate the **LuckyNumber** by **alternatively subtracting and adding** the odd digits as they appear from left to right.
(For example, if the number is 438917, the odd digits are 3, 9, 1, and 7.
So, **LuckyNumber** = $-3 + 9 - 1 + 7 = 12$.)

Write a Java program that reads a number from the user, performs the alternating subtraction and sum of its odd digits, and displays the **Lucky Number**.

Note: You must implement this without converting the integer into a string and without using any string manipulation methods. Use only arithmetic operations to extract each digit. You must use a loop to solve this problem.

Sample Input	Sample Output	Explanation
Enter a positive number: 438917	Lucky Number is: 12	Given number: 438917 Odd Digits : 3,9,1 and 7 LuckyNumber : $-3 + 9 - 1 + 7 = 12$
Enter a positive number: 628	Lucky Number is: 0	Given number: 628 There is no odd digit. So, LuckyNumber=0.
